	4.2	Imputation of qualitative variables	16
5	$\operatorname{Cre}$	eation and discretization of new variables	20
	5.1	New variable: Audi/Not Audi	20
	5.2	New variable: yearsAferSell	22
	5.3	Discretization of the variable Tax	23
	5.4	Discretization of the variable mileage	23
	5.5	Discretization of the variable mpg	23
	5.6	Discretization of the variable year	24

6	Create variable adding the total number missing values, outliers and errors.	24
	6.1 Compute the correlation with all other variables. Rank these variables according the correlation	24
	6.2 Mean of missing/outliers/errors per groups	25
7	Multivariant outliers	26
8	Profiling with FactoMineR	30
	8.1 Profiling of the numeric target variable "price"	30
	8.2 Profiling of the categorical target variable "Audi"	34
1	Data description	
	<ul> <li>Description https://www.kaggle.com/datasets/adityadesai13/used-car-dataset-ford-and-mercedes</li> <li>Data Dictionary - Scraped data of used cars, which have been separated into files corresponding to car manufacturer (only Mercedes, BMW, Volkswagen and Audi cars are to be considered).</li> </ul>	each
1	.1 Variables	
	• Model	
	- A string indicating the model of the car.	
	• Year	
	- A discrete numeric variable to indicate the year the car was sold	
	• Price	
	<ul> <li>Continuous variable indicating the price at which the car was sold</li> </ul>	
	• Transmission	
	<ul> <li>Categorical variable that indicates the type of transmission of the car</li> <li>Values:</li> </ul>	
	* Automatic * Manual	
	* Manual  * Semi-Automatic	
	* Other	
	• Mileage	
	- A discrete numeric variable to indicate the number of miles the car had when it was sold	
	• Fuel Type	
	<ul> <li>Categorical variable that indicates the type of fuel of the car</li> <li>Values:</li> </ul>	
	* Diesel  * Electric	
	* Hybrid	
	* Petrol * Other	
	• Tax	
	<ul> <li>A discrete numeric variable to indicate the road tax of the vehicle.</li> </ul>	
	MPG	
	- Continuous variable indicating the fuel consumption of the car	

Categorical variable that indicates the manufacturer brand of the car.

- Continuous variable indicating the size of the engine

• Engine Size

 $\bullet \quad {\rm Manufacturer}$ 

2

- Values:
  - \* Mercedes
  - \* Audi
  - \* Volkswagen
  - \* BMW

### 2 Loading of Required Packages for the deliverable

We load the necessary packages and set the working directory

#### 2.1 Select a sample of 5000 records

From the proposed database, we need to select a sample of 5000 records randomly so we can start analyzing our data.

```
if (!is.null(dev.list())) dev.off() # Clear plots
rm(list = ls()) # Clean workspace
```

Data: used car dataset.csv

```
# filepath<-'C:/Users/TOREROS-II/Documents/ANDRES/UNI/ADEI/trabajo/deliverable1'
filepath <- "C:/Users/Arnau/Desktop/adei/deliverable1"
df <- read.table(paste0(filepath, "/sample_5000.csv"), header = T, sep = ",")[c(-1)]
# dim(df) # Displays the sample size names(df) # Displays the names
# of the sample variables summary(df)</pre>
```

tinytex::install\_tinytex() ## Some useful functions

```
calcQ <- function(x) {</pre>
    # Function to calculate the different quartiles
    s.x <- summary(x)
    iqr < s.x[5] - s.x[2]
    list(souti = s.x[2] - 3 * iqr, mouti = s.x[2] - 1.5 * iqr, min = s.x[1],
        q1 = s.x[2], q2 = s.x[3], q3 = s.x[5], max = s.x[6], mouts = s.x[5] +
             1.5 * iqr, souts = s.x[5] + 3 * iqr)
countNA <- function(x) {</pre>
    # Function to count the NA values
    mis_x <- NULL
    for (j in 1:ncol(x)) {
        mis_x[j] <- sum(is.na(x[, j]))
    mis_x <- as.data.frame(mis_x)</pre>
    rownames(mis_x) <- names(x)</pre>
    mis_i \leftarrow rep(0, nrow(x))
    for (j in 1:ncol(x)) {
```

```
mis_i <- mis_i + as.numeric(is.na(x[, j]))
}
list(mis_col = mis_x, mis_ind = mis_i)
}
countX <- function(x, X) {
    # Function to count a specific number of appearences
    n_x <- NULL
    for (j in 1:ncol(x)) {
            n_x[j] <- sum(x[, j] == X)
    }
    n_x <- as.data.frame(n_x)
    rownames(n_x) <- names(x)
    nx_i <- rep(0, nrow(x))
    for (j in 1:ncol(x)) {
            nx_i <- nx_i + as.numeric(x[, j] == X)
    }
    list(nx_col = n_x, nx_ind = nx_i)
}</pre>
```

### 3 Univariate Description and Preprocessing

### 3.1 Variable initialization of missings, outliers and errors for columns

```
jmis <- rep(0, 2 * ncol(df)) # columns - variables

mis1 <- countNA(df)
# mis1$mis_ind # Number of missings for the current set of cars
# (observations) mis1$mis_col # Number of missings for the current
# set of variables

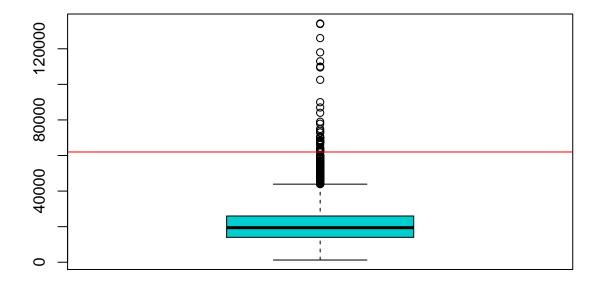

jouts <- rep(0, ncol(df)) # columns - variables

jerrs <- rep(0, ncol(df)) # columns - variables</pre>
```

#### 3.2 Initialization of the response variable Price

We know that the price should be positive, so we will treat as errors the prices  $\leq 0$ . We don't count the errors by rows for the variable price because we erase that rows.

```
summary(df$price)
##
      Min. 1st Qu. Median
                              Mean 3rd Qu.
                                               Max.
                    19430
                              21419 25995 134219
##
      1250
             14000
sel <- which(df$price <= 0)</pre>
jerrs[which(colnames(df) == "price")] <- length(sel)</pre>
# We will delete the rows with errors in the price because we cannot
# make imputations for our target variable.
df <- df[which(df$price > 0), ]
boxplot(df$price, col = "cyan3")
var_out <- calcQ(df$price)</pre>
abline(h = var_out$souts, col = "red")
abline(h = var_out$souti, col = "red")
```

```
# We can see there are outliers in the dataset so we will treat them.
# As this is the response variable, we will delete the outlier rows
# because we cannot delete the value and impute it.
llout_price <- which((df$price > var_out$souts) | (df$price < var_out$souti))
# iouts[llout] <- iouts[llout]+1
jouts[which(colnames(df) == "price")] <- length(llout_price)
df <- df[-llout_price, ]</pre>
```

#### 3.3 Variable initialization of missings, outliers and errors for rows

Initialization of counts for missings, outliers and errors. All numerical variables have to be checked before.

```
imis <- rep(0, nrow(df)) # rows - cars
iouts <- rep(0, nrow(df)) # rows - cars
ierrs <- rep(0, nrow(df)) # rows - cars</pre>
```

### 3.4 Preprocessing of Qualitative/Categorical & Numerical variables

**Description**: We need to do an analysis of all the variables to be able to identify missings, errors and outliers. We will also try to factorize each variable to make it easier to understand the sample.

#### 3.4.1 Model

This variable indicates the model of the car.

```
df$model <- factor(paste0(df$manufacturer, "-", df$model))
# levels(df$model)
summary(df$model)</pre>
```

```

# missing value symbol in R NA assignment for forward imputation:
df[sel, "engineSize"] <- NA
```

# 4 Imputation

What we do with imputation is be able to eliminate all those values that may be missings, outliers or errors to turn them into values that can be realistic within our sample.

### 4.1 Imputation of numeric variables

```
library(missMDA)
# Now one by one describe vars and put them on lists
vars_con <- c("year", "mileage", "tax", "mpg")
vars_res <- c("price")
summary(df[, vars_con])</pre>
```

```

### 6.2 Mean of missing/outliers/errors per groups

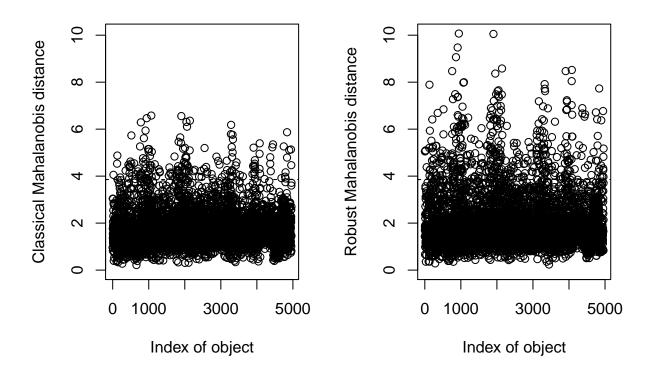

Compute for every group of individuals (group of age, etc,  $\dots$ ) the mean of missing/outliers/errors values. Rank the groups according the computed mean.

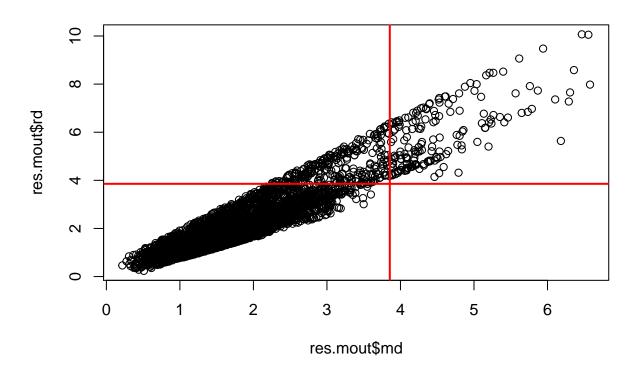

# 7 Multivariant outliers

We don't use the variable tax for the searching of multivariant outliers because it is a column linearly dependent with other column.

```
res.mout <- Moutlier(df[, c(2, 3, 5, 8)], quantile = 0.995)
```

```
par(mfrow = c(1, 1))
plot(res.mout$md, res.mout$rd)
abline(h = res.mout$cutoff, lwd = 2, col = "red")
abline(v = res.mout$cutoff, lwd = 2, col = "red")
```

```
llmout <- which((res.mout$md > res.mout$cutoff) & (res.mout$rd > res.mout$cutoff))

```

The cars with Automatic transmission are overrepresented in multivariant outliers. And also there is a high percentage of automatic cars that are outliers (6.1%) in comparison to cars with other types of transmission. There is a relative low amount of semiautomatic cars that are outliers (20.81%) compared to the global amount of semiautomatic cars (38.45%).

```

With this output we can see from different categories the mean difference in price compared to the mean price of the dataset The cars that have low mpg are more expensive. We can also see that the cars with an engine size = 4 has an estimate of +19400\$ We can also see that the cars with an engine size = 2.9 has an estimate of +19179\$ We can also see that the cars with an model=BMW- 7 Series has an estimate of +18054\$ We can also see that the cars with an engine size = 5.2 has an estimate of +32960\$ We can also see that the cars with an model=VW- Up has an estimate of -17472\$ We can also see that the cars with an engine size = 1.2 has an estimate of -15682\$

### 8.2 Profiling of the categorical target variable "Audi"

```
summary(df$Audi)
```

```
## No Yes
## 3882 1078
```

```
# The 'variable to describe cannot have NA
res.catdes <- catdes(df[, -c(1)], 11, proba = 0.01)
# We exclude the model of the car from the analysis because it
# doesn't bring useful information.
res.catdes$quanti.var # Global association to numeric variables</pre>
```

```
## Eta2 P-value
## mpg 0.012673720 1.837841e-15
## price 0.007068328 3.028155e-09
## mileage 0.002584532 3.412143e-04
```

Miles per galon (mpg), price and mileage are statistically significant variables as they have a p-value less than 0.01. Despite that fact, the effect size associated with them is quite small as they have a small Eta2 value. This means that these variables are not quite significant at predicting if a car is an Audi or not.

```

With this output we can see that Audi cars have a little more price and mileage than the global average and have fewer mpg than the global average. The opposite is true for cars that are not Audi.

```
# mean(df$tax[which(df$Audi=='No')])-mean(df$tax[which(df$Audi=='Yes')])
